

## CS561 Spring 2021 - Systems Project

**Title:** *Implementation a LSM-Tree based key-value store*

**Background:** Log-structured merge-tree (LSM-trees) [1, 2, 3] are one of the most commonly used data structures for persistent storage of key-value entries. LSM-tree-based storages are in use in several modern key-value stores including RocksDB at Facebook, LevelDB and BigTable at Google, bLSM and cLSM at Yahoo!, Cassandra and HBase at Apache, and so on. LSM-trees store data in the disk as immutable logs (also known as sorted sequence tables (SSTs)), which are maintained in hierarchical levels of increasing capacity. To bound the number of logs that a lookup has to probe, LSM-trees merge logs of similar sizes. The two possible merging strategies are (i) leveling (optimized for lookups) and (ii) tiering (optimized for updates).

**Objective:** The objective of the project is to implement a LSM-tree using only a single process thread. The workflow for this is as the following.

- (a) Review LSM-tree literature to understand the principles and operations supported in an LSM-tree
- (b) Implement an LSM-tree (vanilla implementation) using only a single process thread<sup>1</sup> for both merging strategies – leveling and tiering
- (c) Develop by cloning the API available to you at: [https://github.com/midaslab-bu/cs591\\_templatedb](https://github.com/midaslab-bu/cs591_templatedb). Note that you are expected to build a more extensive testing infrastructure.
- (d) Provide us your repository link. The performance of your implementation will be regularly measured, and best performer will be announced on the website.
